Cyclooxygenase enzymes (COX-1 and COX-2) catalyse the production of prostaglandins from arachidonic acid. Prostaglandins are important mediators in the inflammatory process and their production can be reduced by COX-inhibitors. Endocannabinoids, endogenous analogues of the plant derived cannabinoids, occur normally in the human body. The Endocannabinoids are structurally similar to arachidonic acid and have been suggested to interfere with the inflammatory process. They have also been shown to inhibit cancer cell proliferation. Anti-inflammatory effects of cannabinoids and endocannabinoids have been observed, however the mode of action is not yet clarified. Anti-inflammatory activity (i.e., inhibition of COX-2) is proposed to play an important role in the development of colon cancer, which makes this subject interesting to study further. In the present work, the six cannabinoids tetrahydrocannabinol (Δ⁹-THC), tetrahydrocannabinolic acid (Δ⁹-THCA-A), cannabidiol (CBD), cannabidiolic acid (CBDA), cannabigerol (CBG) and cannabigerolic acid (CBGA), isolated from Cannabis sativa, were evaluated for their effects on prostaglandin production. For this purpose an in vitro enzyme based COX-1/COX-2 inhibition assay and a cell based prostaglandin production radioimmunoassay were used. Cannabinoids inhibited cyclooxygenase enzyme activity with IC₅₀ values ranging from 1.7·10⁻⁵ to 2.0·10⁻⁴ M.

Key words cannabinoid; cyclooxygenase inhibition; prostaglandin production
the groups are comparable due to the ring system in cannabinoids, which can be mimicked by the U-shaped endocannabinoids and their four double bonds.10 Also physiologically there are similarities, since both cannabinoids and endocannabinoids bind to the cannabinoid receptors.11 Endocannabinoids, such as anandamide, are derived from arachidonic acid and are structurally similar to this compound (Fig. 1).

Altogether, these similarities gave rise to the hypothesis that cannabinoids can affect the COX enzyme activity. Several studies have demonstrated anti-inflammatory activities in vitro and in vivo for various cannabinoid compounds,12—18 which makes this hypothesis very plausible. Inhibiting effects on COX enzyme activity have also previously been observed for cannabidiol and cannabidiolic acid,17,19 and cannabinoids have potential to affect the potency of NSAIDs.20,21 Furthermore, in recent years, it has been shown that the ECS can protect against colonic inflammation,6,22 which is of interest in prevention of bowel disease and colorectal cancer. The cannabinoid receptors are suggested to be involved in the control of colonic inflammation,6,22 however, the mode of action for the anti-inflammatory effects of cannabinoids is not yet clarified.

In the present study we evaluated the COX-mediated anti-inflammatory properties of six different naturally occurring cannabinoids; tetrahydrocannabinol (Δ²-THC), tetrahydrocannabinolic acid-A (THCA-A), cannabidiol (CBD), cannabidiolic acid (CBDA), cannabigerol (CBG) and cannabigerolic acid (CBGA) (Fig. 1). An enzyme-based in vitro COX inhibition assay was used to evaluate the effects on both COX-1 and COX-2 on enzyme-level, while a cell-based prostaglandin production assay was used to evaluate the effects on COX-2 at cellular level.

MATERIALS AND METHODS

Materials All solvents were purchased from Lab-Scan, Dublin, Ireland, and were of analytical grade. Scientific samples of cannabinoids (Δ²-THC, THCA-A, CBD, CBDA, CBG and CBGA) were provided by Prof. Robert Verpoorte and Dr. Arno Hazekamp, Leiden University, The Netherlands. The cannabinoids were isolated from Cannabis sativa and characterized and quantified using the chromatography and ¹H-NMR methods as described by Hazekamp et al.23,24 All cannabinoid samples were at least 92% pure.

COX-1 enzyme, purified from ram seminal vesicles and COX-2 enzyme, purified from sheep placental cotyledons, and the reference compound NS-398 (N-[2-(cyclo-hexyl- oxy)-4-nitrophenyl]methanesulphonamide) were purchased from Cayman Chemical Co., Ann Arbor, MI, U.S.A. Hematin was obtained from ICN biomedicals Inc., Aurora, Ohio, U.S.A. Adrenalin was purchased from Apoteket AB, Göteborg, Sweden. Reduced glutathione, indomethacine, unlabeled arachidonic acid, anti-prostaglandin E₂, prostaglandin E₂ standard, Bovine Serum Albumin, tumor necrosis factor (TNF)-α and charcoal were obtained from Sigma-Aldrich, St. Louis, MO, U.S.A. ¹⁴C-Arachidonic acid, [5,6,8,11,12,-14,15(n)-³H] Prostaglandin E₂ and dextran molecular weight (mw) 70000 was purchased from Amersham Pharmacia, Stockholm, Sweden, while silica gel 60, particle size 0.063—2 mm was obtained from Merck, Darmstadt, Germany. Dulbecco’s modified Eagle’s medium (DMEM)-high glucose and trypsin-ethylenediaminetetraacetic acid (EDTA) were obtained from Invitrogen, Taastrup, Denmark.

Cell Culture The human colon adenocarcinoma cell line HT29, was cultured in monolayer in DMEM (Dulbecco’s modified Eagle medium supplemented with 10% fetal bovine serum (FBS), 2 mM L-glutamine, and 1% penicillin/streptomycin) at 37 °C and 5% CO₂. All experiments were performed with 60—80% confluent cells and 0.1% DME (0.1% FBS). Pure compounds were dissolved in ethanol and diluted in 0.1% DME (with the final concentration in the cell cultures being maximum 0.25% ethanol).

Enzyme-Based Inhibition Assay The assay followed the original method described by White and Glassman,25 with modifications as described by Noreen et al.26 The assay described below was used for both COX-1 and COX-2 enzymes. In short, 20 μl of each sample was dispensed in a 96-well plate. All samples were dissolved in 20% dimethyl sulfoxide (DMSO) in TRIS buffer. To determine minimal and maximal activity of the enzyme, 20% DMSO in TRIS buffer was used as the sample. Total inhibition of the enzyme in the minimum wells was reached by addition of 10 μl of 2 mM HCl to the wells before the enzyme was added. Cofactors were dissolved in TRIS buffer to concentrations of 1.27 mg/ml hematin, 6.50 mg/ml adrenalin and 1.50 mg/ml glutathione, giving final concentrations in the wells of 1.3 μg/ml, 1.3 mg/ml and 0.3 mg/ml respectively. COX enzyme was mixed with the co-factors, pre-incubated and activated on ice for 5 min. Sixty microliters of enzyme-cofactor solution was added to the sample in the wells, and the plate was incubated for 10 min on ice. The activity of the enzyme in the wells was 6U (COX-1) or 3U (COX-2). Twenty microliters of ¹⁴C- arachidonic acid (¹⁴C-AA) solution was dispensed in each well and to start the enzymatic reaction, the plate was incubated in a 37 °C waterbath for 15 min (COX-1) or 3 min (COX-2). The reaction was stopped by addition of 10 μl of HCl (2 M). To separate the non-converted ¹⁴C-AA from the ¹⁴C-labeled prostaglandins, column chromatography (Silica gel 60, particle size 0.063—2 mm) was used. The columns were equilibrated using 2 ml of eluent, consisting of heptane: ethyl acetate: acetic acid (70:30:1), thereafter the samples were applied, and the non-converted AA was eluted using 4 ml of the same eluent. The prostaglandins were then eluted using 3 ml of a second eluent, consisting of dioxane: methanol (85:15). Scintillation fluid was added to the samples, and the amount of radioactively labeled prostaglandin in the samples was determined using a Packard scintillation spectrometer. Percent inhibition values were calculated and IC50-values were obtained by applying the non-linear regression analysis tool of Graph Pad Prism (GraphPad Software Inc., CA, U.S.A.).
tion was replaced with medium containing 100 μmol/l arachidonic acid (Sigma) and the cells were incubated for 1h. The concentration of released prostaglandin E₂ (PGE₂) was quantified using radio immuno-assay (RIA), according to the protocol supplied by Sigma Chemical Co., using [³H]PGE₂ and polyclonal antiserum to PGE₂ (Sigma). The amount of prostaglandin in each sample was determined using a scintillation counter, and expressed as the percentage inhibition of the TNF-α treated cells. Each cannabinoid was tested at least twice in the cell system and later analyzed in duplicate in the RIA. The results were expressed as the percentage inhibition of the TNF-α treated cells. In all experiments untreated cells were included as controls, and the selective COX-2 inhibitor NS398 was used as a reference compound for comparison of inhibiting activity.

Prior to the PGE2 experiments, all cannabinoid samples were tested for cytotoxicity in the AlamarBlue™ assay to ensure that potential COX-2 inhibitory effects were not due to cell death. 30,31 A cell survival of approximately 70% was considered as acceptable for studying the prostaglandin production. Cannabinoid concentrations causing cell death (i.e., cell survival <70%) were excluded from the PGE₂ production experiments.

RESULTS

Enzyme-Based Inhibition Assay The inhibitory effects of six cannabinoids on the cyclooxygenase enzyme activity was evaluated by an in vitro COX enzyme inhibition assay. Δ⁶-THC, Δ⁹-THCA-A, CBD, CBDA, CBG and CBGA were screened for their ability to inhibit COX-1 and COX-2 at a concentration of 100 mg/ml (approximately 3·10⁻⁴ M), since higher concentrations were assumed to be irrelevant. In this screening, an enzyme inhibition of ≥30% was considered as sufficient to be relevant, and was set as a cutoff limit for compounds to investigate further. Δ⁹-THCA-A, CBDA, CBGA and CBGA showed more than 30% inhibition on COX-1 (Fig. 2). The concentration-dependent activity (i.e. inhibition of COX-1) for these compounds was further evaluated at concentrations ranging from 3.18·10⁻³ to 2.78·10⁻⁵ M, as presented by concentration–effect graphs (Fig. 3A). The IC₅₀-values are presented in Table 1. The IC₅₀-value of the reference compound indomethacin was within acceptable limits of the value reported previously for this COX-1 assay (1.4·10⁻⁶ M),26 confirming that the assay was successful.

When screened for COX-2 enzyme inhibiting activity Δ⁹-THCA-A, CBG and CBGA showed more than 30% inhibition. Interestingly, CBDA, which was recently reported to selectively inhibit COX-2,19 did not reach the 30% inhibition threshold (Fig. 2), and was therefore not considered in our further COX-2 inhibition studies. The inhibition of Δ⁹-THCA-A, CBG and CBGA was measured at concentrations ranging from 3.18·10⁻³ to 2.78·10⁻⁵ M, as represented by the concentration–effect graphs (Fig. 3B) with IC₅₀-values presented in Table 1. The IC₅₀ value of the reference compound indomethacin was within acceptable limits of the value previously reported for this COX-2 assay (1.64·10⁻⁶ M),26 confirming that the assay results were reliable.

of cannabinoids on prostaglandin production were examined in a cell based assay. Six different cannabinoids were tested for their ability to decrease prostaglandin production in TNF-α stimulated HT29 cells. Prior to measuring the prostaglandin production, the effects of cannabinoids on cell survival were investigated, to make sure that the effects were not due to cell death. A cell survival of approximately 70% was considered as acceptable for studying the prostaglandin production, and the observed effects on the PGE₂ production are very unlikely to be explained by cell death. Both apoptosis and necrosis make the cells detach from the plate surface. No such signs were observed. Δ⁹-THC, CBD, CBDA and CBG were tested at concentrations of 2.5 · 10⁻⁵ M, whereas Δ⁹-THCA-A and CBGA were tested at a concentration of 6.25 · 10⁻⁵ M. However, higher concentrations of cannabinoids caused a high cytotoxicity and could not be used in the experiments. The results, as presented in Fig. 4, showed that Δ⁹-THC, Δ⁹-THCA-A, CBD, CBG and CBGA inhibited prostaglandin production, however the level of inhibition was low (<10%). CBDA, on the other hand seemed to stimulate the prostaglandin production (Fig. 4).

**DISCUSSION**

Cannabinoids have been shown to possess anti-inflammatory effects, but the mechanism of action is not yet known. COX enzyme inhibiting activity has previously been observed for CBD and CBDA. Overexpression of COX-2 has in recent years also been associated with colon cancer development, and COX-2 enzyme inhibition is regarded as a potential target for cancer chemoprevention. Interestingly, endocannabinoid levels are elevated in colon cancer tissue, and they also inhibit cancer cell proliferation by acting at cannabinoid receptors. Recently, it has also been shown that the ECS can protect against colonic inflammation, which is of interest in prevention of bowel disease and colorectal cancer. Additionally, cannabinoids have been shown to affect the potency of NSAIDs, potentially via modulation of the COX pathway.

In the present study, six major cannabinoids isolated from plant material modulated the activity of COX enzymes, with IC₅₀ values ranging from 1.7 · 10⁻⁷ to 2.0 · 10⁻⁴ M. None of the cannabinoids showed high COX selectivity except from CBDA, which only inhibited COX-1. This finding is contradictory to previously reported results by Takeda et al., where CBDA was found to be a selective COX-2 inhibitor in an enzyme inhibition assay using purified COX enzymes. These inconsistencies might be caused by differences in the detection method. In the present study radioactively labeled prostaglandin was measured, while Takeda et al. measured the oxidation of TMPD spectrophotometrically. Alternatively, as the cannabinoids used in the studies were purified from plant material, different impurities in the samples could cause different results. Further studies, preferably in human cell lines, are needed to validate the COX inhibition by cannabinoids.

In conclusion, it is clear that cannabinoids inhibit COX enzymes, but in a higher concentration range, as compared to anti-inflammatory drugs (i.e. indomethacin). The obvious contradiction regarding the selectivity for CBDA, as compared to the previous report by Takeda et al., is interesting.

The cannabinoids are known to be involved in the immune system via the CB₂ receptor. The binding constants Kᵢ for Δ⁹-THC interacting with the CB₁ and CB₂ receptors are 8.0 · 10⁻⁵ M and 3.2 · 10⁻⁵ M respectively. These binding constants are in the same range as the IC₅₀ values we found for the COX-inhibition by cannabinoids. This might indicate a possibility of physiologically important effects of the COX-inhibiting cannabinoids via interaction with the COX-enzymes. Further *in vitro* studies are required to prove such effects, but the present study shows that several of the major cannabinoids may also affect other receptors than CB₁ and CB₂. Interestingly, a recent report, linking COX-2 inhibition to increased endocannabinoid levels, suggests the ECS and the COX-mediated prostaglandin pathway to be closely connected.
and should be object for further investigation. Additional studies will also be needed to conclude the relevance of the COX-inhibitory effects in relation to other anti-inflammatory activities mediated by cannabinoids. As evident from recent reports, the ECS plays an important role in the human body. Interestingly, colonic inflammation can be controlled via the ECS, and plant-derived cannabinoids may have a potential to be used as future therapeutic agents.
